1. (a) Basis: when  $n=4$

$$\sum_{i=4}^4 s_{i-4} = s_0 = 1 \quad s_4 - 4 = s_3 + s_0 - 4 = 4 + 1 - 4 = 1$$

$$\therefore \sum_{i=4}^4 s_{i-4} = s_4 - 4 \text{ is true}$$

Assume: it's true for  $n=k$

$$\sum_{i=4}^k s_{i-4} = s_k - 4$$

Induction Step:  $\sum_{i=4}^{k+1} s_{i-4} = \sum_{i=4}^k s_{i-4} + s_{k+1-4}$   
 $= s_k - 4 + s_{k-3}$

$$\because s_n = s_{n-1} + s_{n-4}$$

$$\therefore \sum_{i=4}^{k+1} s_{i-4} = s_k + s_{k-3} - 4  
= s_{k+1} - 4$$

So the statement is true for  $n=k+1$

$$\therefore \sum_{i=4}^n s_{i-4} = s_n - 4 \text{ for all } n \geq 4$$

(b) Basis: ① when  $n=0$

$$s_{0+4} = s_4 = s_3 + s_0 = 5 \quad \hat{\phi}^0 = 1$$

$$s_{0+4} > \hat{\phi}^0$$

② when  $n=3$

$$\begin{aligned} s_{3+4} &= s_6 + s_3 = s_5 + s_2 + s_3 = s_4 + s_1 + s_2 + s_3 \\ &= s_3 + s_0 + s_1 + s_2 + s_3 \\ &= 14 \end{aligned}$$

$$\hat{\phi}^3 \in (1^3, 2^3) \quad \hat{\phi}^3 < 8$$

$\therefore s_{3+4} \geq \hat{\phi}^3$  is true

③ when  $n=1$

$$S_{1+4} = S_5 = S_4 + S_1 = S_3 + S_0 + S_1 = 7$$

$$\hat{\Phi}^1 \in (1, 2)$$

$$\therefore S_{1+4} \geq \hat{\Phi}^1 \text{ is true}$$

④ when  $n=2$

$$S_{2+4} = S_6 = S_5 + S_1 = 8 \quad \hat{\Phi}^2 \in (1, 4)$$

$$\therefore S_{2+4} \geq \hat{\Phi}^2 \text{ is true}$$

Assume : it's true for  $k, k-3$

$$S_{k+4} \geq \hat{\Phi}^k \quad S_{k-3+4} \geq \hat{\Phi}^{k-3}$$

Induction: when  $n=k+1$

$$S_{k+1+4} = S_{k+5} = S_{k+4} + S_{k+1} \\ \geq \hat{\Phi}^k + \hat{\Phi}^{k-3}$$

$$\therefore \hat{\Phi}^k + \hat{\Phi}^{k-3} = (\hat{\Phi}^3 + 1) \cdot \hat{\Phi}^{k-3}$$

$\therefore \hat{\Phi}$  is a root of  $x^4 - x^3 - 1 = 0$

$$\therefore \hat{\Phi}^4 - \hat{\Phi}^3 - 1 = 0$$

$$\therefore \hat{\Phi}^3 + 1 = \hat{\Phi}^4$$

$$\therefore \hat{\Phi}^k + \hat{\Phi}^{k-3} = \hat{\Phi}^4 \cdot \hat{\Phi}^{k-3} = \hat{\Phi}^{k+1}$$

$$\therefore S_{k+1+4} \geq \hat{\Phi}^k + \hat{\Phi}^{k-3} = \hat{\Phi}^{k+1}$$

$$\therefore S_{n+4} \geq \hat{\Phi}^n \text{ for all } n \geq 0$$

2. Mistake is in the induction step.

We can assume  $n=1$ , so the group of 2 horses consists of horse 1 and horse 2.

If we discard horse 2, it's true that horse 1 has same color.

If we discard horse 1, it's also true that horse 2 has same color, which is always true as there is only one horse.

However, in this case, we can not prove that horse 1 and horse 2 have same color. The reasoning process in "Induction Step" is not applicable for this situation. Because there is no such horse that can serve as the "intermediary" to prove the color of the divided sub-groups.

Q3 [10, 36, 25, 54, 37, 12, 75, 68, 42, 86, 72, 90]

Process: 10

$$12) \begin{array}{c} \nearrow 10 \\ 36 \end{array} \Rightarrow \begin{array}{c} 36 \\ / \\ 10 \end{array}$$

$$14) \begin{array}{c} \nearrow 36 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 25 \\ 54 \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 36 \\ \begin{array}{c} \nearrow 54 \quad \nearrow 25 \\ 10 \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 54 \\ \begin{array}{c} \nearrow 36 \quad \nearrow 25 \\ 42 \quad 10 \end{array} \end{array}$$

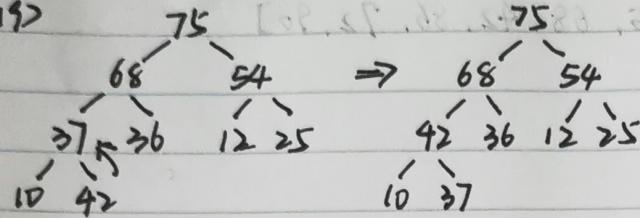

$$15) \begin{array}{c} \nearrow 54 \\ \begin{array}{c} \nearrow 36 \quad \nearrow 25 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 37 \\ 36 \end{array} \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 54 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 25 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \\ 36 \end{array} \end{array} \end{array}$$

$$16) \begin{array}{c} \nearrow 54 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 25 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \\ 36 \end{array} \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 54 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 25 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \\ 36 \end{array} \end{array} \end{array}$$

$$17) \begin{array}{c} \nearrow 54 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 25 \quad \nearrow 75 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \quad \nearrow 12 \quad \nearrow 75 \\ 37 \end{array} \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 54 \quad \nearrow 75 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 75 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \quad \nearrow 12 \quad \nearrow 25 \\ 37 \end{array} \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 75 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 54 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \quad \nearrow 12 \quad \nearrow 25 \\ 37 \end{array} \end{array} \end{array}$$

$$18) \begin{array}{c} \nearrow 75 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 54 \\ \begin{array}{c} \nearrow 10 \quad \nearrow 36 \quad \nearrow 12 \quad \nearrow 25 \\ 68 \end{array} \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 75 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 54 \\ \begin{array}{c} \nearrow 68 \quad \nearrow 36 \quad \nearrow 12 \quad \nearrow 25 \\ 37 \end{array} \end{array} \end{array} \Rightarrow \begin{array}{c} \nearrow 75 \\ \begin{array}{c} \nearrow 68 \quad \nearrow 54 \\ \begin{array}{c} \nearrow 37 \quad \nearrow 36 \quad \nearrow 12 \quad \nearrow 25 \\ 10 \end{array} \end{array} \end{array}$$

The process has been shown above, and I indicate "△" on the 3rd, 6th, 9th and 12th INSERT( ). And The resulting heap is :

Q5

i(a) eg:

i(b) If we want to find the maximum in the heap A, we can just return  $A[1]$ , which is the largest one. The worse-case time is  $O(1)$ .  
The pseudocode is as follows:

HEAP-MAXIMUM (A)

```
if A.heap-size < 1  
    error "heap underflow"  
return A[1]
```

If we want to find the minimum in the heap A. ~~we~~ we can return the smaller one between  $A[2]$  and  $A[3]$ . The worse-case time is  $O(1)$ .

The pseudocode is as follows:

HEAP-MINIMUM (A)

```
if A.heap-size < 1  
    error "heap underflow"  
min = A[1]  
if A.heap-size ≥ 2 and A[2] ≤ min  
    min = A[2]  
if A.heap-size ≥ 3 and A[3] ≤ min  
    min = A[3]  
return min.
```

(c) INSERT(A, key)

if A.heap-size == n

error "heap overflow"

A.heap-size = A.heap-size + 1

A[A.heap-size] = key

INCREASE-KEY(A, key)

INCREASE-KEY(A, key)

find the index i in array A where A[i] == key

level =  $\log_2(i)$

while level > 0

if level % 2 == 0

// even level

if A[i] > A[PARENT(PARENT(i))]

exchange A[i] with A[PARENT(PARENT(i))]

i = PARENT(PARENT(i))

level = level - 2

else if A[i] < A[PARENT(i)]

exchange A[i] with A[PARENT(i)]

i = PARENT(i)

level = level - 1

else break

else

// odd level

if level > 1 and A[i] < A[PARENT(PARENT(i))]

exchange A[i] with A[PARENT(PARENT(i))]

i = PARENT(PARENT(i))

level = level - 2

else if A[i] > A[PARENT(i)]

exchange A[i] with A[PARENT(i)]

i = PARENT(i)

level = level - 1

else break

The running time of INSERT(A, key) is  $O(\log n)$ .

(d)  $\text{Heapify}(A, i)$ :

If  $i$  is at even level:

Let  $A[\text{largest}]$  = the largest node in either left or right subtree.

If  $A[\text{largest}]$  is a grandchild of  $A[i]$ :

if  $A[\text{largest}] > A[i]$ :

Swap  $A[\text{largest}]$  and  $A[i]$ .

if new  $A[\text{largest}] < A[\text{parent of largest}]$ :

Swap  $A[\text{largest}]$  and  $A[\text{parent of largest}]$ .

endif

$\text{Heapify}(A, \text{largest})$ .

endif

else if  $A[\text{largest}] > A[i]$ : #  $A[\text{largest}]$  is a child of  $A[i]$

Swap  $A[\text{largest}]$  and  $A[i]$ .

endif

endif

if  $i$  is at odd level:

... # The algorithm is identical to the above, but with all of the comparison operators reversed.

endif

The running time of the worst-case for  $\text{Heapify}(A, i)$  would be  $O(\log n)$  because running from the root till the leaf nodes level would be the worst case, with  $\log n$  being the height of the heap  $A$ .

(e)

BUILD\_HEAP(A, n)

A.heap\_size = n

for  $j = \lfloor \frac{n}{2} \rfloor$  down to 1

HEAPIFY(A, j)

Analysis of BUILD\_HEAP(A, n):

In level 0, there is 1 node, whose height is  $\log n$ In level 1, there are 2 nodes, whose height is  $\log n - 1$ In the last level, there are at most  $\frac{n}{2}$  nodes, whose height is 1.So the total time  $\leq 1 \cdot \frac{n}{2} + 2 \cdot \frac{n}{2^2} + \dots = \sum_{i=1}^{\log n} i \cdot \frac{n}{2^i} = S$ 

$$S = 1 \cdot \frac{n}{2} + 2 \cdot \frac{n}{2^2} + 3 \cdot \frac{n}{2^3} + \dots$$

$$\frac{1}{2}S = 1 \cdot \frac{n}{2^2} + 2 \cdot \frac{n}{2^3} + \dots$$

$$\frac{1}{2}S = S - \frac{1}{2}S = \frac{n}{2} + \frac{n}{2^2} + \frac{n}{2^3} = n(\frac{1}{2} + \frac{1}{2^2} + \frac{1}{2^3} + \dots) \leq n$$

$$\Rightarrow S = 2n = O(n)$$

As a result, the running time of BUILD\_HEAP() is  $O(n)$ .

(f) EXTRACT\_MAX(A)

max = HEAP\_MAXIMUM(A)

A[1] = A[A.heap\_size]

A.heap\_size = A.heap\_size - 1

HEAPIFY(A, 1)

return max

EXTRACT\_MIN(A)

min = HEAP\_MINIMUM(A)

find the index i in array A where  $A[i] == min$ 

A[min] = A[A.heap\_size]

A.heap\_size = A.heap\_size - 1

HEAPIFY(A, i)

return min

The running time of EXTRACT\_MAX(A) and EXTRACT\_MIN(A) is  $O(\log n)$ .

6. We assume input array is A, the value ~~is~~ k is what we need to compare x to the k-th largest element, and i is the index of array.

We'll call the function on the loop.

The ~~pseudo~~ pseudo code is as follows:

```
compare (array A, int i, int k, int x, int &count)
```

```
if i > A.heap-size
```

```
    return
```

```
if A[i] > x
```

```
    return
```

```
    count = count + 1
```

```
if count >= k
```

```
    return .
```

```
compare (A, LEFT(i), k, x, count) ;
```

```
compare (A, RIGHT(i), k, x, count) ;
```

```
return ;
```

```
main-function (array A, int k, int x)
```

```
count = 0
```

```
compare (A, 0, k, x, count)
```

```
if count >= k
```

```
    return true
```

```
else
```

```
    return false
```

We call the function on the loop until count is larger or equal to k, ~~or A[i] > x~~ or  $A[i] > x$ .

So the running time is at most ~~O(k)~~,  $O(k)$ , and the extra space is at most  $O(k)$ .
